

Predicting NFL Draft Surplus Value via Gated Neural Networks

STAT 421 — NFL Combine Project Midpoint Showcase

A) Later rounds exhibit much wider wAVOE spread, with occasional extreme surplus-value hits alongside many misses. B) Career wAV declines sharply with pick number, but the LOWESS curve highlights persistent pockets of outliers far above expectation. C) Combine-wAVOE correlations differ by position group, with lower times in speed/agility drills generally aligning with higher surplus value where those skills are most position-relevant. D) Within-round hit rates vary meaningfully by pick quartile, suggesting that surplus value is concentrated in specific parts of the board rather than uniformly spread across each round.
